I observed the behavior of a ceiling fan during its operation. When the fan was switched on at a low speed, the blades rotated slowly and produced minimal airflow. As the speed regulator was increased, the fan rotated faster, creating stronger airflow and better cooling. I also noticed a slight humming sound at higher speeds and mild vibration after continuous use.

The changes occur because increasing the regulator setting allows more electrical power to reach the motor, causing the blades to spin faster. The humming sound and vibration may be due to the motor working harder, dust accumulation on the blades, or slight imbalance in the fan blades.
