In the last 24 hours, I noticed that I had left the fan, lights, and mosquito repellent machine running in my room while I was having lunch in the hall. This happened in the afternoon when the weather was quite hot, so I tend to keep the fan running to maintain a cool room. However, I also realized that the mosquito repellent, which is usually not needed during the daytime, was unnecessarily left on until lunch.

To handle the situation, I switched off all the appliances once I noticed they were running without any use. After that, I made a conscious effort to check everything before leaving the room, even for short durations.

Technology could help solve this problem through smart automation systems. For example, motion sensors could detect when the room is unoccupied and automatically turn off the fan, lights, and mosquito repellent. Additionally, smart plugs or switches connected to a mobile app could allow scheduling—so the mosquito repellent turns on only during the night—and also enable remote control to switch off devices if forgotten. This would reduce electricity wastage while maintaining comfort and proper usage.
